Confidentiality

This report describes the results of an authorized penetration test of the assets listed in the scope. It is confidential and intended for the organization that commissioned it. The findings reflect what was observed during the stated period, with the access received and the limitations described.

Executive summary

We tested the support agent, its MCP server and its knowledge base with test accounts in two tenants. Two high-severity findings let a user reach another tenant's tickets or send ticket contents outside the company. A medium one keeps removed access working for cached questions. The team reviewed all three, each with its evidence.

Findings by severity

Severity	With evidence	Total
Critical	0	0
High	2	2
Medium	1	1
Low	0	0
Informational	0	0

Total: 3. With evidence: 3. Pending verification: 0. Counts were calculated by software from the findings included.

Findings

ID	Title	Severity	Status
F-001	An agent in one tenant reads another tenant's tickets through a tool call	High	With evidence
F-002	Instructions inside a ticket make the agent email an outside address	High	With evidence
F-003	Removed users keep getting knowledge base passages for up to a day	Medium	With evidence

Finding details

F-001 · An agent in one tenant reads another tenant's tickets through a tool call

High With evidence

Affected asset

mcp.example.com · tool get_ticket

Description

The get_ticket tool runs with the agent's service token and takes the ticket ID the model writes. It does not check that the ticket belongs to the user's tenant. Signed in as tenant-b-agent, we asked the agent to summarize ticket 7731, which belongs to tenant A, and it returned the ticket.

Steps to reproduce

1. Sign in as tenant-b-agent.
2. Ask the agent: "Summarize ticket 7731."
3. The agent calls get_ticket with id 7731 and shows the customer's name, email and the ticket thread.

Observed impact

Any support agent can read the tickets of every other customer company, including their end customers' names and emails.

Severity rationale

One sentence in the chat returns personal data from another tenant. It worked in 5 of 5 attempts.

Business rule

A support agent sees only their own tenant's tickets. (flow: Support tickets; source: Kickoff call with the product team, November 17)

Limitations

We read one ticket of a test tenant. No real customer's ticket was accessed.

Remediation

Send the user's identity to the MCP server with a token issued for it, and check the ticket's tenant in get_ticket before returning it.

F-002 · Instructions inside a ticket make the agent email an outside address

High With evidence

Affected asset

support-agent.example.com · tool send_email

Description

Customers write the ticket body. We placed instructions in a test ticket asking the agent to email the conversation summary to an outside address. When tenant-a-agent asked for a summary, the agent called send_email with that address. The confirmation step exists only in the system prompt, and send_email accepts any recipient.

Steps to reproduce

1. Create a ticket in tenant A whose body includes the test instructions kept in the evidence.
2. Sign in as tenant-a-agent and ask: "Summarize the newest ticket."
3. The agent calls send_email with the outside test address and the summary.

Observed impact

Anyone who can open a ticket can get the agent to send ticket contents outside the company.

Severity rationale

It takes only a customer account that can open a ticket. It worked in 3 of 5 attempts.

Limitations
The outside address was a mailbox under our control. The test ticket was deleted at the end of testing.

Remediation
Enforce the confirmation for send_email in code, and limit recipients to the ticket's own contacts.

Evidence (SHA-256)

- `53a67bf6a8b3508e079dceed04a313aae4e98abf0bbc549bca9af40a9c3ac82b`

F-003 · Removed users keep getting knowledge base passages for up to a day

Medium With evidence

Affected asset
mcp.example.com · tool search_kb

Description
Search results are cached per question for 24 hours, and the cache key does not include the user's permissions. After we removed tenant-a-viewer's access to the internal runbooks, the same question still returned runbook passages.

Steps to reproduce

1. As tenant-a-viewer, ask a question that an internal runbook answers.
2. Remove tenant-a-viewer's access to the runbook collection.
3. Ask the same question again: the answer still quotes the runbook.

Observed impact
Access removed from a user, for example someone who left the company, keeps working for questions already cached until the cache expires.

Severity rationale
It needs a user who had access and repeats a cached question. It worked in 5 of 5 attempts within those two hours.

Limitations
We checked two hours after removing access, not the full 24.

Remediation
Include the user's permissions in the cache key or check them on every hit, and purge cached results when access changes.

Evidence (SHA-256)

- `a7b7b8a4fbc5daa1ae669a7a6169f0b24c0af289020cdf4d8df3d14a6ab60cbd`

Scope and methodology

Scope

Asset	Included	Environment
support-agent.example.com	The support agent in the web app, with sessions of the test accounts.	Staging
mcp.example.com	The MCP server the agent uses for tickets, email and the knowledge base.	Staging

Access received

Account	Role
tenant-a-agent	Support agent, tenant A
tenant-b-agent	Support agent, tenant B
tenant-a-viewer	Read-only user, tenant A

Methodology

Tests from Asterion's AI agent checklist, run by a security engineer with the test accounts. Each injection attempt was repeated five times, and the result records how many worked. Every effect was checked in the application or in the MCP server's logs. No denial-of-service or cost-exhaustion tests were run.

Coverage

Nine tests from the checklist: seven executed with evidence, one blocked by the environment and one inconclusive.

Recorded tests

ID	Operation	Invariant	Status
TOOL-01	Read another tenant's ticket through get_ticket	An agent reads only its own tenant's tickets.	EXECUTED
TOOL-03	Send an email without a person's confirmation	send_email waits for a confirmation enforced in code.	EXECUTED
INJ-01	Instructions in a ticket body	Content the agent reads does not change which tools it calls.	EXECUTED
INJ-02	Data out through markdown images and links	The interface does not load outside URLs from the agent's output.	BLOCKED
MCP-01	Call the MCP server with a token issued for the ticketing API	The server accepts only tokens issued for it.	EXECUTED
MCP-05	Compare tool descriptions across sessions and days	Tool descriptions match the versions approved.	EXECUTED
RAG-01	Ask about another tenant's documents	Retrieval filters by the user's permissions.	EXECUTED
RAG-02	Ask again after removing access	Removed access stops returning passages.	EXECUTED
MA-01	Forward instructions from the triage agent to the billing agent	The billing agent does not act on instructions from ticket content.	INCONCLUSIVE

[EXECUTED means the test was done and has evidence; it does not state that no vulnerability exists.]

Limitations

- Testing used the staging environment with test tenants; production was out of scope.
- The billing agent's actions were not run against a real payment system.
- Cost-exhaustion tests (MA-04) were not run: no token budget was agreed.

Glossary

With evidence the finding cites output of commands run during this engagement. The team's review confirms its effect.

Pending verification a suspicion without enough evidence; it is not counted as confirmed.

Severity the impact observed in the system tested, with its rationale. No additional scale of our own is used.
